ABSTRACT

The main objective of educational institutions is to provide high quality of education. Providing a high quality of education depends on predicting the unmotivated students and motivates them before they enter into the final examination. There are so many factors which leads to unmotivated the students, such as college infrastructure, their living area, family annual income, Parents qualification, Past academic performance, students own interest on the course, other habits of the student, etc., There are many researches undertaken on the above factors and predict the unmotivated students, In this paper we mainly focus on how the geographical region plays a role on student's academic performance.

Keywords: Educational Data mining, Classification, Hidden naive Bayes, Place based learning.

INTRODUCTION

Educational data mining is a new research area that utilizes statistical, machine learning and data mining algorithms over the different types of educational data. The main objective of the Educational data mining is to adapt and solve the research issues on educational data and understand the students settings in which they learn. EDM allows discovering new knowledge based on students' usage data; it helps to validate/evaluate educational systems and to potentially improve some aspects of the quality of education, and to lay the groundwork for more effective learning process.

To provide a high quality of education, it is important to identify the unmotivated students and motivate them before they enter into the final exam. Generally Students' academic performance is based upon diverse factors like personal, social, psychological and other environmental variables[8][9][10]. A promising tool to attain this objective is the use of Data Mining. Data mining techniques are used to operate on large amount of data to discover hidden patterns and relationships which are helpful in decision making. Classification is a predictive data mining technique which makes prediction about values of data using known results found from different data [1].

In this study, we investigate how geographical region will make an impact on student's academic performance. Generally there is a myth called rural students are good in studies but have a less presentation skills, similarly urban students may or may not be good in studies but they have a good presentation skills and through this knowledge, Based on their presentation skills, they get more academic performance than rural students. Through this study we analyse the performance of rural and urban students

In this study, we use random forest algorithm to classify the student dataset and then perform the Welch's unpaired t-test analysis to perform the significant difference among the study.

RELATED WORKS

Although Educational data mining is a recent research field, there are many related research works done in this area, that is because of its vast potential to educational institutes. [2] which clearly indicates that rural and urban students are different in their learning styles and it suggest that students in rural schools appear to be more concerned and engaged in the educational process than urban students. Barcinas [3] indicates that students from the two areas are quite different in ethnicity. The rural students appears to be quite homogeneous, however the urban students seemed to have a greater mix of race and cultures. The lack of opportunity for rural students to interact with persons of varying backgrounds may be a limiting factor in their educational and sociological development and the educational level of the parents was higher in urban areas than in rural areas. Urban parents were more likely to expect their children to advance their education beyond high school. All these factors shows the difference in their social context between rural and urban areas. These differences help to explain the aspirations of students and finally the work suggests that students from rural areas should learn to live and work in an urban area. Bhardwaj and Pal [4] concluded that students living location are highly correlated with the student's academic performance.

DATA MINING PROCESS

In this study, we have collect data from Hindusthan College of Arts & Science, Coimbatore, Tamilnadu, India. These data are analyzed using classification method to predict the student's performance. In order to apply this technique following steps are performed in sequence:

DATA PREPARATIONS

In our comparison we collect details from First Year and Second year students of MCA, Hindusthan college of Arts & Science- Coimbatore in the period of 2012-2013. Initially student dataset contains 200 record and 18 Attribute.

Table 1: Students dataset description.

Attribute	Description	Possible Values
SSLC_Place	SSLC Area of Study	{Rural, Urban}
SSLC_Grade	Grade Obtained in SSLC	{Distinction ≥ 80 & <100% First ≥ 60 & <80% Second ≥ 45 & <60% Third ≥36 & <45%}

ISSN 2278-3083

International Journal of Science and Applied Information Technology (IJSAIT), Vol.2 , No.2, Pages : 20 - 23 (2013)
Special Issue of ICA4E 2013 - Held during 15-16 April, 2013 in Singapore

HSC_Study	HSC Area of Study	{Rural, Urban}
HSC_Grade	Grade Obtained in HSC	{Distinction ≥ 80 & <100% First ≥ 60 & <80% Second ≥ 45 & <60% Third ≥36 & <45%}
UG_Study	UG Area of Study	{Rural, Urban}
UG_Grade	Grade Obtained in UG	{Distinction ≥ 80 & <100% First ≥ 60 & <80% Second ≥ 50 & <60% Third ≥40 & <49%}
Status	Performance Status of the Student	{Improved, Decreased, No Change, Not Stable}

Table 1 represents the attributes and their description of the final database for classifying the student's dataset. As a part of the data preparation and pre-processing of the dataset and to get better input data for data mining techniques, we have done some pre-processing for the collected data before loading the data set to the data mining software, irrelevant attributes should be removed. The attributes used in Table-I are processed via the Weka software to apply the data mining methods on them. The attributes such as the Student_Name , Student_rollno, Semester, SSLC_ School_name, UG_School_name, Degree, HSC_School_name are not selected to be a part of the mining process; this is because they do not provide any knowledge on the data set processing and they present personal information of the students, also they have very large variances or duplicates information which make them irrelevant for data mining. In the above dataset Status is declared as a Response variable.

MODEL CONSTRUCTION

To classify Student's dataset, we use WEKA tool[6]. The WEKA Tool is an Open Source software which is fully implemented in the Java programming language and runs on any modern computing platform, it contains a comprehensive collection of data pre-processing and modelling techniques. Weka supports several standard data mining tasks like data clustering, classification, regression, pre-processing, visualization and feature selection. These techniques are predicated on the assumption that the data is available as a single flat file or relation.

After Pre-processing the data using Weka, rural.arff and urban.arff is created. rural.arff contains the data of students who did their study in rural area. urban.arff contains the data of students who did their study in urban area. Those files are loaded into WEKA explorer. The classify panel enables the user to apply classification and regression algorithms to the resulting dataset, to estimate the accuracy of the resulting predictive model, and to visualize erroneous predictions, or the model itself. We used Random Forest Under the "Test options", the 10-fold cross-validation is selected as our evaluation approach. Since there is no separate evaluation data set, this is necessary to get a reasonable idea of accuracy of the generated model.

Table 2 : Classifiers Accuracy using Random Forest Algorithm

	Correctly Classified Instances	**In Corrected Classified Instances**
Rural Students	27	6
Urban Students	72	2

Table 2 shows the classifiers accuracy of the given dataset using random forest algorithm.

Table 3: Classification matrix - Rural Students

Status		Predicted			
		Decreased	No Change	Improved	Not Stable
Actual	Decreased	2	0	1	0
	No Change	0	5	1	0
	Improved	0	0	18	1
	Not Stable	1	1	1	2

Table 3 shows the classification matrix for the Rural students dataset using Random Forest algorithm.

Table 4:- Classification matrix - Urban Students

Status		**Predicted**			
		Decreased	**No Change**	**Improved**	**Not Stable**
Actual	Decreased	17	0	0	0
	No Change	0	24	0	0
	Improved	0	0	27	0
	Not Stable	0	1	1	4

Table 4 shows the classification matrix for the Urban students dataset using Random Forest algorithm.

Table 5 : Classifier Results (Rural Students)

Status	**Precision**	**Recall**
Decreased	0.67	0.67
No Change	0.83	0.83
Improved	0.86	0.94
Not Stable	0.67	0.4
Overall Accuracy		0.818

ISSN 2278-3083

International Journal of Science and Applied Information Technology (IJSAIT), Vol.2 , No.2, Pages : 20 - 23 (2013)
Special Issue of ICA4E 2013 - Held during 15-16 April, 2013 in Singapore

Table 5 shows that the overall accuracy is 0.818 which is greater than 0.5. hence the accuracy is very good.

Table 6 : Classifier Results (Urban Students)

Status	Precision	Recall
Decreased	1	1
No Change	0.96	1
Improved	0.96	1
Not Stable	1	0.67
Overall Accuracy		0.973

Table 6 shows that the overall accuracy is 0.818 which is greater than 0.5. hence the accuracy is very good.

MEASURING KAPPA STATISTIC

Cohen's kappa measures the agreement between two raters, who each classify N items into C mutually exclusive categories.

The equation for κ is:

$$\kappa = \frac{Pr(a) - Pr(e)}{1 - Pr(e)}$$

where Pr(a) is the relative observed agreement among raters, and Pr(e) is the hypothetical probability of chance agreement, using the observed data to calculate the probabilities of each observer randomly saying each category.

$$Pr(a) = \frac{(2 + 5 + 18 + 2)}{33} = 0.8182$$

$$Pr(e) = \frac{3}{33}*\frac{3}{33} + \frac{6}{33}*\frac{6}{33} + \frac{19}{33}*\frac{21}{33} + \frac{5}{33}*\frac{3}{33}$$

$$Pr(e) = 0.4215$$

$$\kappa = \frac{0.8182 - 0.4215}{1 - 0.4215} = 0.6857$$

Kappa Coefficient value for Rural Students is 0.6857 and the calculation shows that there is 95% confidence interval:

$$Pr(a) = \frac{(17 + 24 + 27 + 4)}{74} = 0.9730$$

$$Pr(e) = \frac{17}{74}*\frac{17}{74} + \frac{24}{74}*\frac{25}{74} + \frac{27}{74}*\frac{28}{74} + \frac{6}{74}*\frac{4}{74}$$

$$Pr(e) = 0.3048$$

$$\kappa = \frac{0.9730 - 0.3048}{1 - 0.3048} = 0.9611$$

Kappa Coefficient value for Urban Students is 0.9611 and the calculation shows that there is 95% confidence interval:

EXPERIMENTAL RESULTS

In Addition to the above data mining process, we have conducted the Welch's unpaired t-test analysis to find out the student academic score based on their area of study.

The following table describes the Welch's unpaired t-test analysis between Rural & Urban students.

Table 7 : t-test between Uniform study area and Academic Score

A.Score / Study Area	N	Mean	SD	t-value	p-value
Rural	33	61.66	6.26	-5.562	0.000*
Urban	74	66.74	6.58		

P-value is tested at 5% level

Among the total number of students considered for this study, 107 students were belonging to uniform group, which means (SSLC, HSC and College in uniform area). There are 33 students belonging to Rural area, 74 of them belonging to Urban area and their mean, standard deviation respectively 61.66±6.26, 66.74±6.58; t-value is -5.562, p-value is less than the level of significance 0.05, hence it is concluded that there is a significant difference of academic score present between rural and urban students.

CONCLUSION

Through this study, the work found that there a significant difference between the urban and rural students. In this paper, we evaluate only the students who completed their studies in uniform area, and there is another case that how the performance of the students who completed their studies in mixed area, Whether such students make any impact in educational settings. We strongly suggests that the upcoming study is based on students academic performance based on mixed study area.
